

## Report

EAST-WEST GATEWAY
St. Louis Metropolitan Area

## Regional Congestion

## Report

[^0]The East-West Gateway Council of Governments (EWG) hereby gives public notice that it is the policy of the agency to assure full compliance with Title VI of the Civil Rights Act of 1964, the Civil Rights Restoration Act of 1987, Executive Order 12898 on Environmental Justice, and related statutes and regulations in all programs and activities. Title VI requires that no person in the United States of America shall, on the grounds of race, color, sex, or national origin, be excluded from the participation in, be denied the benefits of, or be otherwise subjected to discrimination under any program or activity for which EWG receives federal financial assistance. Any person who believes they have been aggrieved by an unlawful discriminatory practice under Title VI has a right to file a formal complaint with EWG. Any such complaint must be in writing and filed with EWG's Title VI Coordinator within one hundred eighty (180) days following the date of the alleged discriminatory occurrence. For more information, or to obtain a Title VI Discrimination Complaint Form, please see our web site at http://www.ewgateway.org or call (314) 421-4220

APPENDICES ..... 68

## 1 Introduction

The regional Congestion Management Process (CMP) is a systematic and regionally accepted approach for managing congestion that provides accurate and up-to-date information on transportation system performance. As an MPO for the St. Louis region with a population over 200,000, East-West Gateway is required to maintain a CMP as part of its ongoing transportation planning process.

The CMP is intended to be a systematic way of monitoring, measuring and diagnosing the causes of current and future congestion on a region's multi-modal transportation systems; evaluating and recommending alternative strategies to manage current and future regional congestion; and monitoring and evaluating the performance of strategies implemented to manage congestion.

The purpose of the MPO transportation planning process is to comprehensively consider possible strategies, evaluate projects from diverse viewpoints, and meaningfully involve key stakeholders to support strategic regional choices in congestion management, such as improving roadways, expanding transit capacity, encouraging bicycling, and ensuring safe walking environments. These congestion management strategies provide a connecting tissue between the Long-Range Transportation Plan (LRTP), the Transportation Improvement Plan (TIP), and the regional Intelligent Transportation Systems (ITS). The CMP is strongly connected to the LRTP by providing a set of congestion management objectives, performance measures, and strategies that make the plan comprehensive.

The CMP provides system performance information in evaluating projects nominated for inclusion in the TIP and the CMP objectives are integrated with the application scoring and prioritization process. Transportation systems management and operation for congestion management are implemented through Intelligent Transportation Systems (ITS) such as traffic signal improvements; traveler information projects; electronic fare systems, Automatic Vehicle Identification (AVI), and Automatic Vehicle Location (AVL) technologies. Also, proposed ITS projects are required to be consistent with the regional CMP strategies.

The 2017 Regional Congestion Report is comprised of six parts. The first three parts of the report deal with the extent of the monitored CMP network, performance measures employed, and data sources used, respectively. The fourth part explores roadways that pose significant mobility challenges. The fifth section summarizes the findings of the region's congested locations. The sixth section evaluates the impact of mobility-enhancing projects embarked upon by our partners. Finally, the report concludes with broader changes in congestion between 2016 and 2017.

## 2 Identify Congested CMP Network

For the purposes of this analysis, the morning peak-period is from 6 am to 9 am and the evening peakperiod is from 3 pm to 6 pm . The source of data is explained in detail in part 4. All performance measures are calculated and compared based on data from these time periods. The process of identifying the congested network for this analysis involved a detailed visual inspection of Speed Index congestion on all National Highway System (NHS) roadways in the region depicted on the NHS map. This index is the ratio of average speeds to 85th-percentile speed, which represents free-flow speeds. Four thresholds are applied to the Speed Index to reveal the various categories of congestion from the system for both arterials and freeways.

The following two maps (Figures 1 and 2) aim to show the spatial extent of the CMP network considered for measuring congestion in the region rather than as an assessment of congestion. Of the 2,533 congested CMP network miles, arterials accounted for 1,641 miles while freeways represented 892 miles.

This inspection resulted in selection of congested roadways by direction and peak time (see Tables 1 and 2). These tables list the locations on both freeways and arterials that meet these criteria for the 3 hour AM or PM peak period. Arterials accounted for 81 miles of the congested roadways while freeways represented 285 miles. Some of these congested location are construction related. Appendix 2 outlines the work zones that may have congestion effects.

### 2.1 Selected Congested Locations on Arterials

Figures 7 to 18 show the spatial distribution of Speed Index in the region by peak time. The figures depict the hourly progression of congestion in contrast to the performance measures which are calculated based on the 3 hour peak periods. They depict how the congestion increases and decreases during the peak hours at the various locations. Please note that some locations on these maps show as congested for short periods that are not included in the list of congested locations because they do not meet the thresholds for the 3 hour peak.

## Arterial Congestion Thresholds (Speed Index)

| Severe | Heavy | Moderate | Light |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |
| $0 \%$ | $44 \%$ | $53 \%$ | $74 \%$ | $100 \%$ |

### 2.3 Percent of Miles Congested

Figures 19 to 22 depict the extent of congestion for each hour of the AM and PM peak periods. The extent of congestion is measured by Speed Index thresholds (see sections 2.1 and 2.2). The percentages are calculated based on the compilation of all the congested locations that occur during each hour of the peak periods.

## Arterials

No significant change in congestion patterns for each hour of peak period was observed between 2016 and 2017. Regional congestion can conveniently be classified as being moderate. The shares of heavy congestion saw increases across all periods. Severe congestion shares declined during morning peak periods but saw a slight increase in the evening peak period (see Figures 19 and 20).

Figure 19: Percent of Miles of Congested Arterials (2017)

Figure 20: Percent of Miles of Congested Arterials (2016)

## Freeways

Regional freeways are mostly moderately congested. Evening peak hour moderate congestion levels have increased since 2016. The share of queue lengths considered heavy during PM peak hours saw declines since 2016. It appears that morning peak hours are becoming heavily congested (see Figures 21 and 22).

Figure 21: Percent of Miles of Congested Freeways (2017)

Figure 22: Percent of Miles of Congested Freeways (2016)

### 2.4 Freeway Congestion Intensity and Duration

A congestion scan is a graphic representation of how congestion on a corridor varies by location and time of day. Time of day is shown on the horizontal axis by hour for the entire day. Location along the corridor is shown in miles on the vertical axis and is referenced to intersecting roadways. Congestion is represented using the same color coding that is used for the congestion maps contained in this report. The resulting visual shows where congestion occurs along the corridor, the intensity of the congestion and the time of day it occurs. The solid yellow and red bands represent continuous congestion along a corridor with the width of a band showing the length of time that the congestion occurs and the length of a band showing the distance in miles of the congestion. Figures 23 to 30 show the space-time representation of freeway congestion.

## 3 Performance Measures

Performance measures are key components of the CMP process as they:

- characterize existing and anticipated conditions on the regional transportation system;
- track progress toward meeting regional objectives;
- identify specific locations with congestion to address; and
- assess congestion mitigation strategies, programs, and projects.

Six performance measures were analyzed in this study. These are Average Speed, Speed Index (SI), Planning Time Index (PTI), and Travel Time Index (TTI). These performance measures are defined below.

- Average Speed is the number of miles a vehicle is driven in an hour.
- Speed Index is the ratio of average speeds to $85^{\text {th }}$-percentile speeds of a segment.
- Travel Time Index is Travel Time represented as a percentage of the ideal travel time. For example, a TTI value of 1.2 means travel time during peak period is $20 \%$ longer than the freeflow travel time between the same origin and destination.
- Planning Time Index is the total travel time that should be planned when extra time (buffer time) is included in the trip. For example, a Planning Time Index of 1.60 means that, for a 15 -minute trip, the total time that should be planned for the trip is 24 minutes ( 15 minutes x $1.60=24$ minutes). In this scenario, the buffer time alone is 9 minutes ( 15 minutes x 0.6 percent). The higher the Planning Time Index, the more unreliable travel time is.
- Percent of Person-Miles Traveled (PMT) on the Interstate that are reliable. PMT is the product of Annual Traffic Volumes, Segment Length, and Vehicle Occupancy for segments that have Level Of Travel Time Reliability (LOTTR) that is less than 1.5 . The result is expressed as a percent of Total PMT.
- Percent of Person-Miles Traveled on the Non-Interstate that are reliable.

## 4 Collect Data / Monitor System Performance

Following the establishment of indicators for measuring system performance, the next important task is to collect data on these performance measures. The HERE data set was used to analyze the identified performance measures. HERE is a private vendor that provides mapping data and related services to individuals and companies. MoDOT has contracted with HERE for access to their data and the use of the Regional Integrated Transportation Information System (RITIS). RITIS is an automated data sharing, dissemination, and archiving system that includes many performance measures, dashboard, and visual analytics tools housed at the University of Maryland. MoDOT's contract provides the same access to Missouri MPOs, which gives EWG the ability to analyze the HERE data set for the entire eight-county region.

In order to better understand regional congestion problems and needs we undertook three major tasks. These included developing a regional system performance report, ranking all the congested locations, and analyzing regional system performance trends.

## a) Regional Performance Measures

Performance measures analyzed here represent average annual weekday data. Tables 3 and 4 provide peak period system performance information. They list all locations in our region that exceed the performance measure thresholds established for congestion during the 3-hour AM and PM peak periods. Detailed hourly variations for each congested location within each peak period are appended to this report (Appendix 1). These tables are included to show how congestion varies throughout the peak period for each location.

Table 3: Arterial Performance Measures (Annual Weekday)

| No. | Route | Limits | Direction | State | Peak | Queue <br> Length | BT | BTI | PT | PTI | Speed | TT | TTI |

b) Rank Congested Locations

We ranked all congested locations identified in Tables 1 and 2 based on severity, total impact and variability. These are defined as follows:

- The Severity number is the average of the TTI and PTI. It takes into account two aspects of congestion; the average delay of a congested location and how reliable that average is from day to day. Higher Severity numbers reflect more severe congestion.
- The Total Impact number is obtained by multiplying the congested miles of a location by the TTI. Its purpose is to compare the impact to the driver by factoring in the comparative lengths of the queues in each congested location.
- The Congestion Variability number is the ratio of PTI to TTI. Higher variability values indicate more variation in travel times and lower values show less variation in travel times from day to day.

Locations were ranked with 1 being the worst condition and the highest numbered location in the list being the least severe of the congested locations. This ranking exercise helps in determining which segments rank the highest in terms of congestion relief needs. Tables 5 to 8 below show congested location ranking analysis for arterials and freeways.

The average length of regional arterial congestion in 2017 was 1.55 miles. The top 10 severely congested locations had 1.03 miles of average congestion, $34 \%$ lower than the average for the region. The top 10 most impactful locations had a combined length of congestion of 3.43 miles, more than doubled the regional average length of congestion. The most unreliable arterial locations had an average length of congestion of 1.25 miles, accounting for about $20 \%$ less than the average length of regional arterial congestion. Finally, the most impactful arterial congestion accounted for more than one-half of length of congestion (see Table 5).

Table 5: Length of Congestion on Top 10 Locations (Arterials)

| Ranking | Avg. QL | Total QL | \% QL |
| :--- | ---: | ---: | ---: |
| Severity | 1.03 | 10.31 | $18 \%$ |
| Total Impact | 3.43 | 34.32 | $60 \%$ |
| Variability | 1.25 | 12.47 | $22 \%$ |
| Avg QL (ALL) | 1.55 | - | - |
| Total |  | $\mathbf{5 7 . 1}$ | $\mathbf{1 0 0 \%}$ |

The average length of freeway congestion was higher in the top 10 severely congested locations than for all congested freeway locations. The top 10 most impactful locations had an average length of congestion that was 4 miles more than the regional average length of congestion. Less dependable locations had a length of congestion that was slightly lower than the regional freeway average. Thus, most severe and less dependable freeways accounted for about $75 \%$ of length of congestion (see Table 6).

Table 6: Length of Congestion on Top 10 Locations (Freeways)

| Ranking | Avg. QL | Total QL | \% QL |
| :--- | ---: | ---: | ---: |
| Severity | 7.14 | 71.44 | $32 \%$ |
| Total Impact | 9.77 | 97.72 | $43 \%$ |
| Variability | 5.59 | 55.91 | $25 \%$ |
| Avg QL (ALL) | 5.87 | - | - |
| Total |  | $\mathbf{2 2 5 . 0 7}$ | $\mathbf{1 0 0 \%}$ |

Table 7: Ranking of Congested Arterial Locations by Severity, Total Impact and Variability

Trend analysis is an important analytical technique to gauge the performance of regional congestion indices. This analysis was undertaken for five congestion indices. These are average Speeds, Travel Time Index, Planning Time Index, and Person-Miles Traveled (PMT, Interstate and Non-Interstate). The forecast was undertaken using Statistical Analysis System's (SAS) AutoRegressive Integrated Moving Average (ARIMA) model. The ARIMA procedure is used for analyzing and forecasting equally spaced univariate time series data. The trend analysis was undertaken for the entire monitored system.

Detailed examination of regional congestion trends, between 2012 and 2017, indicate that while arterial congestion appears to be increasing, freeway mobility is improving. The general deterioration in arterial mobility had a negative effect on TTI and PTI. Between 2012 and 2017, arterial TTI increased between $5 \%$ (morning peak) and $15 \%$ (evening peak). At the same time, morning peak PTI registered an increase of $9 \%$ in the morning peaks and $23 \%$ during evening peaks.

The reduction in regional freeway congestion is reflected in the rise in speeds and decline in TTI \& PTI. Between 2012 and 2017, freeway speeds increased from 58.6 to 64.1 (morning peak) and from 57.3 to 63.8 (evening peak); TTI declined from 1.05 to 0.97 (morning peak) and from 1.08 to 0.97 (evening peak); and PTI dropped from 1.16 to 1.08 (morning peak) and from 1.27 to 1.12 (evening peak).

The ARIMA forecasts reveal a consistent pattern of future performance trajectories for regional speeds and PTI. Both morning and evening peak speeds on arterials and freeways were forecasted to increase between 2018 and 2019. Similarly, PTI forecasts portray a downward trend by 2019. However, the future TTI and PMT values are mixed. All TTI forecasts indicate a downward trend, except for evening peak prediction which showed an upward movement. While the percent of Person-Miles Traveled on the interstate that are reliable showed signs of decline, PMT on non-interstates increased marginally. These findings are shown from figures 31-43.

Figure 34: PM Freeway Speeds

ii. Travel Time Index (TTI)

Travel Time Index is often confused with Travel Times. While Travel Time measures the overall time spent traveling from one location to the other, Travel Time Index measures Travel Time as a percentage of free-flow time. This way, the Travel Time Index can be used as a proxy to measure congestion. The peak period TTI (observed and forecast) for arterials and freeways are shown from figures 35-38.

iii. Planning Time Index (PTI)

Planning Time Index is the most widely used measure of travel time reliability. Planning Time Index (PTI) is the total travel time that should be planned when an adequate buffer time is included in a trip's travel time. It is measured as the ratio of 95th percentile Travel Time to Free-flow Travel Time, and it captures both typical and unexpected delay. This way, the PTI compares near-worst case travel time to a travel time in free-flow traffic. The observed trend and forecast of PTI are shown from figures 39-42.

Figure 44: Percent of Person-Miles Traveled on the Non-Interstate That Are Reliable

## 6 Findings

## a) Regional Congested Locations Summary

Congested locations identified in Tables 1 and 2 are summarized in the following graphs in terms of peak hour and miles of congestion. A comparison of between 2017 and 2016 data was undertaken to gauge broader congestion changes. The total congestion in 2016 for arterials and freeways was 81 miles and 285 miles, respectively. In 2017, the total congestion for arterials ( 92 miles) was about one-half of the queue length on freeways ( 188 miles).

For arterials, as shown in Figures 45, congestion continues to be a problematic phenomenon during evening peak hours. Although regional arterial congestion increased by 11 miles between 2016 and 2017, evening peak congestion's share of the increase was marginal. Morning peak periods registered significant increase in congestion between 2016 and 2017.

Figure 45: Congested Arterials (2016-17)

Generally, regional freeway queue length trend observed in 2017 is consistent with what was found in 2016 (see Figure 46). The distribution of freeway peak-hour congestion is the same between 2016 and 2017, despite the significant reduction in congestion from 285 miles in 2016 to 188 miles in 2017. Evening peak hours continue to dominate the share of total congestion (60\%).

Figure 46: Congested Freeways (2016-17)

b) Congested Location Performance Comparisons

Comparative analysis of ranked congested location is a very fruitful exercise to identify changes in congestion (queue length) over time. Between 2016 and 2017, the number of congested arterial locations increased from 38 to 59 , resulting in a concomitant increase in total congestion miles from 81 miles to 99 miles. For freeways, the situation was a little different. The number of congested freeway locations declined from 37 to 32 along with a huge decline in total congested miles (from 285 to 188).

The previous section ranked congested locations in terms of Severity, Total Impact, and Variability. In this section, the ranking analysis was summarized on a scale of low (up to $33^{\text {rd }}$ percentile), medium ( $34^{\text {th }}$ to $66^{\text {th }}$ percentile) and high (greater than $67^{\text {th }}$ percentile) ranges. This way it was possible to compare rankings in different years. The following section summarizes the findings from the ranking exercise. Summary graphs for congested location rankings are shown in figures 5-6 for arterials and 7-8 for freeways. The graphs depict the percent of total congested miles that fall in each of the low, medium and high ranges for each ranking category. The list of locations falling under each category can be found in Appendix 3 (Tables 44 to 55).

## Arterial Findings

The increase in arterial severity of congestion led to expected increase on road user impact and variability (reliability) of the system (see Figures 47 and 48).

## Severity

- Low level of severity increased by $7 \%$ ( $35 \%$ to $42 \%$ ).
- Moderate and high severity of congestion reduced from $65 \%$ to $58 \%$.

## Total Impact

- All categories remained constant, except the moderate group with a slight increase of $1 \%$.

## Variability

- Low and moderate categories had a total increase of $14 \%$ in 2017.
- Locations with very high degrees of unreliability declined from $37 \%$ (2016) to $23 \%$ (2017).

Figure 47: Arterial Congested Location Comparisons (2017)

Figure 48: Arterial Congested Location Comparisons (2016)

## Freeway Findings

All ranking categories in 2017 experienced decline or stayed the same. The freeway data revealed fewer congested locations and shorter queue lengths but less than proportionate decline in driver impact and reliability (see Figures 49 and 50).

## Severity

- Congestion severity remained the same for moderate and high locations.

## Total Impact

- Congestion had less impact on drivers (moderate and high congestion declined from $83 \%$ in 2016 to $80 \%$ in 2017).

## Variability

- The freeway System was a little more reliable (moderate and high congestion declined from $69 \%$ in 2016 to $68 \%$ in 2017).

Figure 49: Freeway Congested Location (2017)

Figure 50: Freeway Congested Location (2016)

c) Congested Location Performance Distributions

This section looks at changes in ranked locations between 2016 and 2017. Locations were ranked for Severity, Total Impact, and Variability. The x-axis represent the position of congested locations in that category. The $y$-axis measures the score of a particular congested location on that category.

## a) Arterials

## i. Severity

- The level of severity of congestion increased across all ranked locations between 2016 and 2017.

Figure 51: Severity of Arterial Congestion (2016-17)

## ii. Total Impact

- The level of congestion impact on drivers increased for the majority of ranked locations between 2016 and 2017.

Figure 52: Impact of Arterial Congestion (2016-17)

## Variability

- The level of unreliability of congested locations worsened between 2016 and 2017.

Figure 53: Reliability of Arterial Congestion (2016-17)

## b) Freeways

The insert tables in the following graphs show the percent change of average score for major freeways between 2016 and 2017.

## i. Severity

- The level of severity of congestion increased for the most severely congested locations.

Figure 54: Severity of Freeway Congestion (2016-17)

## ii. Total Impact

- The degree of impact of congestion on drivers declined between 2016 and 2017.

Figure 55: Impact of Freeway Congestion (2016-17)

## iii. Variability

- There was no significant degree of change between 2016 and 2017 in freeway reliability of travel times.

Figure 56: Variability of Freeway Congestion (2016-17)

Following the implementation of mobility-enhancing projects, partners are often required to evaluate strategies to ensure that implemented strategies are effective at addressing congestion as intended, and to make changes based on the findings as necessary. Strategies that significantly improve congestion are encouraged in future project sponsorship.

These mobility project evaluations are undertaken with a before-and-after study design. The following sub-section reports mobility project evaluations from the Missouri Department of Transportation (MoDOT), Illinois Department of Transportation (IDOT), and St. Charles.
a) Missouri Department of Transportation (MoDOT)

MODOT implemented six key projects with significant impacts on delay, number of stops, average speed, and travel times. These projects were on the following roadways: Route K, MO-100, MO-115, I-64, US50, and MO-267. The detailed before-and-after congestion and emission impacts are summarized in the following sections. Also, the results of I-64 lane addition impact analysis was reported.

## 1. Route K

## Congestion Impacts of Route-K Signal Timing Projects

Following the completion of the implementation phase, the field studies were repeated in order to evaluate the effectiveness of the new coordination plans. These travel time delay studies were again repeated numerous times over the course of two weeks. The data for each set of travel runs is provided in Table 9.

Table 9: Congestion Impacts of Route-K Signal Timing Projects

| Time Period | Scenario | Total Delay |  | Stops |  | Average Speed (mph) |  | Travel Time (sec) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | NB | SB | NB | SB | NB | SB | NB | SB |
| AM | Before | 243 | 205 | 5.5 | 3.7 | 31 | 32 | 774 | 739 |
|  | After | 158 | 196 | 4 | 4.8 | 36 | 34 | 662 | 697 |
|  | Improvement | -35\% | -4\% | -27\% | 30\% | 17\% | 6\% | -14\% | -6\% |

Source: Missouri Dept. of Transp. (St. Louis), Signal Timing and Optimization (Route K), Final Report, September 2017, p. 15.
As seen in Table 11, the final timings resulted in significant improvements in total delay, stops, average speed, and travel times on the corridor due to improved progression. The study corridor experienced noteworthy improvements: decreases in delay, stops and travel time and increases in average speed for both directions during all time periods. The only exception was the southbound stops during the AM Peak. Specifically, delay reductions ranged between $4 \%$ and $61 \%$, Travel Times reductions ranged between $6 \%$ and $27 \%$, and average speeds increased between $6 \%$ and $36 \%$.

## Fuel and Emission Benefits of the Improved Signal Timings

As a final step in this analysis, net savings in annual operating costs and pollutant emissions were estimated using FHWA guidelines ("A Method for Estimating Fuel Consumption and Vehicle Emissions on Urban Arterials and Networks," Report Number FHWA-TS-81-210; April 1981). These computations were based upon average travel times, speed measurements and daily traffic volumes. The results are summarized in Table 10.

Table 10: Fuel and Emission Benefits

| Emission Measure | Pre-Study | Post-Study | Difference |
| :--- | ---: | ---: | ---: |
| Est. Annual Fuel Consumption (gal/yr) | $6,652,835$ | $6,066,805$ | 586,030 |
| Est. Annual Operating Costs (\$/yr) | $15,434,577$ | $14,074,988$ | $1,359,589$ |
| Est. Annual VOC Emissions (lbs/yer) | 243,900 | 218,201 | 25,699 |
| Est. Annual CO Emissions (lbs/yer) | $1,052,121$ | 941,180 | 110,941 |
| Est. Annual NO Emissions (lbs/yer) | 204,614 | 183,118 | 21,496 |
| TOTAL VOC/CO/NO Emissions (lbs/yr) | $\mathbf{1 , 5 0 0 , 6 3 5}$ | $\mathbf{1 , 3 4 2 , 4 9 9}$ | $\mathbf{1 5 8 , 1 3 6}$ |

Source: Missouri Dept. of Transp., St. Louis, Signal Timing and Optimization (Route K), Final Report, September 2017 , p. 16.
Calculations of existing conditions indicated that approximately $6,652,835$ gallons of fuel were consumed annually and that approximately $1,500,635$ pounds of pollutants were emitted each year within the corridor. Measurements of the net increase in travel speeds were used to determine that approximately 586,030 gallons of fuel could be saved each year by the improved coordination. This reduced fuel consumption would result in an annual cost savings of approximately $\$ 1,359,590$ (assuming an average fuel price of $\$ 2.32$ per gallon). In addition, pollutant emissions would be decreased by 158,136 pounds per year.

## I-64 land Addition Impact Analysis

## Eastbound Westbound I-64 Lane Addition Impact Analysis

## What was the problem?

During the morning and evening commutes, much of I-64 was congested between I-270 and Route 340 (Olive Boulevard/Clarkson Road). Nearly 150,000 vehicles travel this section of roadiway, and in 20 years, that number is expected to increase to more than 175,000 vehicles. The levels of eastbound congestion in the morning and westbound congestion in the evening were cause for improvements along this corridor.

BEFORE

AFIER

With the addition of the new 5th lane on Eastbound I-64 between Route 141 and I-270, the offramp to Maryville Center and the on-ramp before Mason Road moved further to the east:

- Eastbound I-64 average speeds have increased in both AM and PM Peaks
- Average speeds have become more stable during $A M$ and $P M$ peaks
- Drivers should expect to see smoother traffic conditions

With the Westbound I-64 lane addition from I-270 to Route 340 :

- Westbound $l-64$ average speeds have increased in both $A M$ and $P M$ Peaks
- Traffic has metered closer to $1-270$

See the following two pages for AMPM Peak speed data charts. Future reports will contain analysis of traffic volume data.

Figures 57 and 58: I-64 Eastbound Speed Impact Analysis

Figures 59 and 60: I-64 Westbound Speed Impact Analysis

## 2. MO-100

## Congestion Impacts of MO-100 Signal Timing Projects

The travel time delay studies indicated that the flow of end-to-end traffic through the corridor improved throughout the day. The travel delays were performed during the month of February 2017 with the PCTravel software package and GPS units. Multiple runs were performed in each direction on a typical weekday during the morning, midday, and afternoon peak periods. The results of the timing changes are shown in Table 11.

Table 11: Congestion Impacts of MO-100 Signal Timing Projects

| Time Period | Scenario | Stops |  | Average Speed (mph) |  | Travel Time (sec) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | EB | WB | EB | WB | EB | WB |
| AM | Before | 15.4 | 8.6 | - | - | - | - |
|  | After | 5.8 | 6.2 | - | - | - | - |
|  | Improvement | -62\% | -28\% | +1.2\% | +0.7\% | -4.0\% | -1.9\% |

|  | After | 8.2 | 8.6 | - | - | - | - |
|  | Improvement | -39\% | -40\% | +0.4\% | +1.8\% | -1.2\% | -6.6\% |

Source: Missouri Depart. of Transp., Route 100 Timing Improvement Project, Final Report, CBB\# 39-16, April 2017, p. 39.

## Fuel and Emission Benefits of the Improved Signal Timings

As a final step in this analysis, net savings in annual operating costs and pollutant emissions were estimated using FHWA guidelines ("A Method for Estimating Fuel Consumption and Vehicle Emissions on Urban Arterials and Networks," Report Number FHWA-TS-81-210; April 1981). The formulas used in these computations were based upon average travel times, speed measurements and daily traffic volumes. The results are summarized in Table 12.

Calculations of the existing conditions indicated that approximately $15,008,535$ gallons of fuel were consumed annually and that over 5,104,230 pounds of pollutants were emitted each year within the corridor. Measurements of the net increase in travel speeds were used to determine that 280,270 gallons of fuel could be saved each year by the improved coordination. This improved fuel consumption would result in an annual operating cost savings of approximately $\$ 639,016$ (assuming an average fuel price of $\$ 2.28$ per gallon). In addition, pollutant emissions would be decreased by 206,586 pounds per year.

Table 12: Fuel and Emission Benefits

| Emission Measure | Pre-Study | Post-Study | Difference |
| :--- | ---: | ---: | ---: |
| Est. Annual Fuel Consumption (gal/yr) | $15,008,535$ | $14,728,265$ | $-280,270$ |
| Est. Annual Operating Costs (\$/yr) | $34,219,460$ | $33,580,444$ | $-639,016$ |
| Est. Annual VOC Emissions (lbs/yer) | 495,471 | 473,504 | $-21,967$ |
| Est. Annual CO Emissions (lbs/yer) | $3,689,145$ | $3,505,196$ | $-183,949$ |
| Est. Annual NO Emissions (lbs/yer) | 919,614 | 918,944 | -670 |
| TOTAL VOC/CO/NO Emissions (lbs/yr) | $\mathbf{5 , 1 0 4 , 2 3 0}$ | $\mathbf{4 , 8 9 7 , 6 4 4}$ | $\mathbf{- 2 0 6 , 5 8 6}$ |

## 3. $\mathbf{M O}-115$

## Congestion Impacts of MO-115 Signal Timing Projects

As seen in Table 13, the final timings resulted in significant improvements in total delay, stops, average speed, and travel times on the corridor due to improved progression. Travel times were reduced between $7 \%$ and $30 \%$, delay between $51 \%$ and $83 \%$, and average speeds increased by $7 \%$ to $42 \%$.

Table 13: Congestion Impacts of MO-115 Signal Timing Projects

| Time Period | Scenario | Total Delay |  | Stops |  | Average Speed (mph) |  | Travel Time (sec) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | EB | WB | EB | WB | EB | WB | EB | WB |

Source: Missouri Depart. of Transportation, MO 115 Signal Optimization Project (J6S3120), Final Report, October, 2017, p. 16.

## Fuel and Emission Benefits of the Improved Signal Timings

Calculations of existing conditions indicated that approximately $1,604,285$ gallons of fuel were consumed annually and that approximately $3,324,899$ pounds of pollutants were emitted each year within the corridor. Measurements of the net increase in travel speeds were used to determine that approximately 182,415 gallons of fuel could be saved each year by the improved coordination (see Table 14).

Table 14: Fuel and Emission Benefits

| Emission Measure | Pre-Study | Post-Study | Difference |
| :--- | ---: | ---: | ---: |
| Est. Annual Fuel Consumption (gal/yr) | $1,604,285$ | $1,421,870$ | 182,415 |
| Est. Annual Operating Costs (\$/yr) | $4,251,355$ | $3,767,956$ | 483,400 |
| Est. Annual VOC Emissions (lbs/yer) | 296,973 | 242,589 | 54,384 |
| Est. Annual CO Emissions (lbs/yer) | $2,848,932$ | $2,687,845$ | 161,088 |
| Est. Annual NO Emissions (lbs/yer) | 178,994 | 148,741 | 30,253 |
| TOTAL VOC/CO/NO Emissions (lbs/yr | $\mathbf{3 , 3 2 4 , 8 9 9}$ | $\mathbf{3 , 0 7 9 , 1 7 5}$ | $\mathbf{2 4 5 , 7 2 5}$ |

## 4. I-64

## Congestion Impacts of I-64 Signal Timing Projects

The "floating car" technique was used to conduct the "before" and "after" travel time and delay studies. Travel time and delay studies along the study corridors were collected using a GPS device and the GPS software Tru-Traffic. Travel time studies were conducted during the following peak hour periods:

- AM Peak: 7:00 AM - 9:00 AM
- Mid-Day Peak: 11:00 AM - 1:00 PM
- PM Peak: 4:00 PM - 6:00 PM
- Weekend: 11:00 AM - 1:00 PM

The delay output by Tru-Traffic is based on a specified "normal speed". The "normal speed" is defined by the software as the speed at which a non-delayed vehicle would be considered to be traveling. The normal speed was input as the posted speed limit. The number of stops output by Tru-Traffic is based on a specified "stop speed value". When the vehicle falls below the stop speed value, the vehicle is considered stopped. The stop speed value was kept at the default value of 5 mph .

Travel time studies were conducted for 23 different movements during each of the four peak periods, which resulted in 92 different travel time runs. The results of the "before" and "after" travel time and delay studies conducted with the Tru-Traffic software show that 52 of the 92 directional travel times were reduced when comparing the "before" and "after" travel time data. Of those $52,38(73 \%$ of the reduced runs) were greater than $20 \%$. Of the 92 travel time runs, nearly $65 \%$ showed a reduction or no change in the travel time from the "before" condition. Table 15 summarizes the results of the travel time studies conducted during each of the peak periods.

Table 15: Congestion Impacts of I-64 Signal Timing Projects

| Time Period | Reduced Delay | Reduced Delay <br> $(>\mathbf{2 0 \%})$ | Increased <br> Delay | Increased <br> Delay <br> $(<\mathbf{1 0 \%})$ | No <br> Change | Total |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| AM Peak | 14 | 9 | 6 | 3 | 3 | 23 |
| Midday Peak | 13 | 11 | 9 | 0 | 1 | 23 |
| PM Peak | 15 | 12 | 8 | 4 | 0 | 23 |
| Weekend | 10 | 6 | 10 | 1 | 3 | 23 |
| Total | 52 | 38 | 33 | 8 | 7 | 92 |

Source: Missouri Depart. of Trans., I-64 Interchanges Signal Optimization (Final Version 2.0), Final Report, March, 2017, p. 25.

## Fuel and Emission Benefits of the Improved Signal Timings

Utilizing the differences in "before" and "after" travel time runs and peak hour traffic volumes, annual fuel cost savings and emissions reductions were calculated for the peak hours. The general methodology, fuel consumption factors, and health costs of motor vehicle emissions are based on Caltrans' California Life-Cycle Benefit/Cost Analysis Model Version 5.0 (Cal-B/C). Emission values used in the calculations were obtained from the California Air Resource Board.

Assumptions were also made as to the cost of a gallon of gas and the value of an hour of an individual's time for the travel time and fuel consumption benefit calculations. For the week of implementation of the new timings, Iteris staff paid $\$ 2.09$ per gallon, which was used to calculate the average fuel savings. The value of an hour of time was assumed to be the average hourly wage for the Saint Louis metropolitan area based on statistics provided by the Bureau of Labor Statistics for May 2015, in which the average hourly wage was $\$ 22.69$. The fuel and emission reduction effects are shown in Table 16.

Table 16: Fuel and Emission Benefits

| Benefit | 1-Year (\$) | 5-Years (\$) |
| :--- | ---: | ---: |
| Travel Time Savings | $238,131.55$ | $595,328.88$ |
| Fuel Savings | $27,419.06$ | $68,547.64$ |
| ROG Emissions Reduction | 78.64 | 196.61 |
| Nox Emissions Reduction | $1,193.71$ | $2,984.29$ |
| PM10 Emissions Reduction | 886.02 | $2,215.06$ |
| CO Emissions Reduction | 42.91 | 107.26 |
| Total Benefits | $267,751.89$ | $669,379.73$ |

Final Report, March, 2017, p. 32.

## 5. US-50

## Congestion Impacts of US-50 Signal Timing Projects

The table below shows the average before and after travel times for the US 50 corridor through Union. Decreases in travel times were achieved in both directions during the AM Peak, while only one direction saw an improvement in the MD and PM Peaks. In both of those peaks, simultaneous green bands were difficult to achieve between the two MO-47 intersections and one direction was chosen as the primary direction to provide arterial priority. In the PM Peak, the westbound direction has a higher traffic volume and was selected for priority. In both cases, the direction with the improved travel time saw greater increase than the decline of the opposite direction (see Table 17).

Table 17: Congestion Impacts of US-50 Signal Timing Projects

| Direction | Time Period | Before | After | Difference <br> $(\%)$ |
| :---: | :--- | ---: | ---: | ---: |
|  | AM Peak | $5: 55$ | $5: 38$ | $-6 \%$ |
|  | Midday Peak | $5: 44$ | $4: 58$ | $-13 \%$ |
|  | PM Peak | $5: 30$ | $6: 30$ | $18 \%$ |
| WB | AM Peak | $5: 51$ | $5: 39$ | $-3 \%$ |
|  | Midday Peak | $5: 39$ | $5: 58$ | $6 \%$ |
|  | PM Peak | $6: 48$ | $5: 21$ | $-21 \%$ |

Source: Missouri Depart. of Trans., US Highway 50, Franklin County (Union, MO), Signal Optimization, Final Report, April, 2017, p. 28.

## Fuel and Emission Benefits of the Improved Signal Timings

Fuel consumption and vehicle emissions data were obtained from Synchro, and are summarized in the tables below for the existing and proposed conditions. A reduction in fuel consumption was achieved for each peak period, as well a reduction in vehicle pollutant emissions (see Table 18).

Table 18: Fuel and Emission Benefits

| Emission Measure | Pre-Study | Post-Study | Difference |
| :--- | ---: | ---: | ---: |
| Est. Annual Fuel Consumption (gal/yr) | 342,940 | 318,864 | $-24,076$ |
| Est. Annual Operating Costs $(\$ / \mathrm{yr})$ | 713,315 | 663,237 | $-50,078$ |
| Est. Annual VOC Emissions $(\mathrm{kg} / \mathrm{yer})$ | 5,554 | 5,165 | -389 |
| Est. Annual CO Emissions $(\mathrm{kg} / \mathrm{yer})$ | 23,965 | 22,287 | $-1,678$ |
| Est. Annual NO Emissions $(\mathrm{kg} / \mathrm{yer})$ | 4,663 | 4,338 | -326 |

6. MO-267

## Congestion Impacts of MO-267 Signal Timing Projects

The table below shows the average before and after travel times for the MO-267 corridor. Decreases in travel time were achieved in one direction for each travel time period. The traffic volumes are higher in the northbound direction in the AM Peak and higher in the southbound direction in the PM Peak (see Table 19).

Table 19: Congestion Impacts of MO-267 Signal Timing Projects

| Direction | Time Period | Before | After | Difference <br> $(\%)$ |  |
| :---: | :--- | ---: | ---: | ---: | :---: |
|  | AM Peak | $6: 11$ | $6: 08$ | $-1 \%$ |  |
|  | Midday Peak | $6: 14$ | $5: 54$ | $-5 \%$ |  |
|  | PM Peak | $6: 29$ | $6: 34$ | $1 \%$ |  |
| SB | AM Peak | $6: 34$ | $6: 52$ | $5 \%$ |  |
|  | Midday Peak | $6: 44$ | $7: 03$ | $5 \%$ |  |
|  | PM Peak | $6: 54$ | $6: 50$ | $-1 \%$ |  |

## Fuel and Emission Benefits of the Improved Signal Timings

Fuel consumption and vehicle emissions data were obtained from Synchro, and are summarized in the table below for existing and proposed conditions. A reduction in fuel consumption was achieved for each peak period, as well a reduction in vehicle pollutant emissions (see Table 20).

Table 20: Fuel and Emission Benefits

| Emission Measure | Pre-Study | Post-Study | Difference |
| :--- | ---: | ---: | ---: |
| Est. Annual Fuel Consumption $(\mathrm{gal} / \mathrm{yr})$ | 246,168 | 240,500 | $-5,668$ |
| Est. Annual Operating Costs $(\$ / \mathrm{yr})$ | 512,029 | 500,240 | $-11,789$ |
| Est. Annual VOC Emissions $(\mathrm{kg} / \mathrm{yer})$ | 4,498 | 4,390 | -108 |
| Est. Annual CO Emissions $(\mathrm{kg} / \mathrm{yer})$ | 19,410 | 18,947 | -463 |
| Est. Annual NO Emissions $(\mathrm{kg} / \mathrm{yer})$ | 3,775 | 3,686 | -88 |
| TOTAL VOC/CO/NO Emissions $(\mathbf{k g} / \mathbf{y r})$ | $\mathbf{2 7 , 6 8 2}$ | $\mathbf{2 7 , 0 2 3}$ | $\mathbf{- 6 5 9}$ |

## 7. MoDOT Incident Management

Incident management is essential in congestion management owing to the positive relationship between incidence and recurring congestion, especially during peak periods. In 2017, the mean number of incidents and standard deviation stood at 883 and 84 , respectively. At the same time, the Time to Clear Incidents (TTCI) was 26 minutes, with a standard deviation of 1.7 (see Figure 61). Further exploration of the data shows TTC to be stable even when the number of incidents grow sharply.

Figure 61: Number of Incidents and Time to Clear (2017)

Source: MoDOT Quarterly Regional Mobility Report
b) Illinois Department of Transportation (IDOT) (District 8)

The Illinois Department of Transportation (IDOT) has been very effective in making sure their ITS infrastructure is up-to-date. In pursuance of this, a number of importance changes were undertaken in 2017. These include:

- New IP Cameras were installed under maintenance at fifteen locations. Fourteen of these were replacing broken analog cameras, and one was at a new location on the Stan Bridge DMS. With the new cameras, a new image delivery process was established for the cameras to create and send an image file directly to the ftp server that stores images for the various websites.
- 76 H 30 was completed. New DMS and two new cameras on 255.
- In January, we unplugged the speed map that had been displaying inaccurate information in our TMC. We used a decommissioned pc to display Google's traffic layer and refresh regularly. This provides a real time visual for our dispatchers to notice any severe congestion in the area. We also display this map in the main lobby.
- AVL was added to EPV radios as part of a pilot project with Motorola and D1.
- An interagency agreement was signed between IDOT and SIUE to allow SIUE to host the D8 traveler information website, stl-traffic.com. Development of the new site began late in 2017. This work will be completed in 2018.
- New pump station SCADA connected into our ITS network with a monitoring system in the TMC.
- Re-established connectivity to the ISP D11 dispatch center here in our shared building. This had been down for several years.
- Coordinated fiber disconnect and planned reconnect for the PSB slide.
- Outside of the metro, in Calhoun County, we upgraded the outdated traffic monitoring system on the Joe Page Bridge with new cameras. The cameras there were over twenty years old and did not provide clear or color images. We installed a new NVR system that allows monitoring for the drawbridge operations and added the ability to record and store video. (Shortly after the system was installed, a truck crashed into a traffic signal and kept going. The truck along with the company was identified by these recordings.)

## c) St. Charles County

The majority of Gateway Green Light Phase 3 construction was completed in 2017. This contract included approximately 8 miles of fiber optic backbone communication links on three corridors including New Town Blvd/Elm Pointe Industrial Drive in St. Charles, Lake St. Louis Blvd/Technology Drive in Lake St. Louis, Veterans Memorial Pkwy/Wilmer Road/Interstate Drive in Wentzville, and Main Street/Tom Ginnever Road in O'Fallon. Additionally, 30 wireless vehicle travel time detectors, 34 CCTV cameras, 9 count stations and 2 dynamic message signs were installed throughout the county. As a whole these network connections and devices have significantly improved the ability to monitor, manage, and change traffic signal timings along regional arterials in real time to provide optimum traffic signal operations and promote efficient flows. The Gateway Green Light operator has continued to provide peak hour, event, and incident monitoring in order to move traffic efficiently during the most congested periods.

The tables in this section provide a high level comparison of regional congestion from 2016 to 2017 based on the data developed in the Annual Regional Congestion reports. Tables 21 thru 23 list the top ten freeway congested locations for each ranking category. The red highlighted entries are reoccurring locations with the exact same limits in both years. The green highlighted entries are locations that also reoccur, but their limits vary somewhat from 2016 to 2017. Tables 24 through 26 make the same comparisons for the arterial congested locations.

Table 27 shows the percent change in the average ranking scores of the congested locations for each interstate corridor from 2016 to 2017. Table 28 shows the percent change in the number of congested miles from 2016 to 2017 on each Interstate corridor. This analysis shows a reduction from a total of 265 congested miles on the interstate corridors in 2016 to a total of 176 in 2017, a reduction of $33 \%$ which is a significant change.

A review of Interstate highway work zones in these two years indicates that the reduction of work zone impacts from 2016 to 2017 likely played a significant role in the reduced congestion impacts. In 2016 there were 11 projects that significantly affected peak hour traffic on the interstates. These work zones affected parts of the I-44, I-55, I-64, I-70, I-170, and I-270 corridors contributing significantly to regional congestion. Comparatively, in 2017 there were only 3 projects that significantly affected congestion on the I-44 and I-64 corridors. In addition, completion of two of the projects in 2016 further reduced congestion due to improvements made. These are added lanes on I-64 west of I-270 both eastbound and westbound and added lane southbound on I-55 north of Route Z.

b. Change in Congestion Ranking Score

Table 27: Change in Congestion Ranking Score on Each Interstate Corridor (2016-17)

| No. | Route | Severity | Total Impact | Variability |
| :---: | :--- | ---: | ---: | ---: |
| 1 | $\mathrm{I}-44$ | $23 \%$ | $-34 \%$ | $6 \%$ |
| 2 | $\mathrm{I}-55$ | $-9 \%$ | $-47 \%$ | $2 \%$ |
| 3 | $\mathrm{I}-64$ | $-2 \%$ | $-26 \%$ | $-2 \%$ |
| 4 | I-70 | $-6 \%$ | $-23 \%$ | $-3 \%$ |
| 5 | $\mathrm{I}-170$ | $18 \%$ | $-28 \%$ | $6 \%$ |
| 6 | I-270 | $8 \%$ | $-4 \%$ | $1 \%$ |

- I-44 and I-170 are increasingly more severely congested.
- All major freeways have had significant reduction in impact on drivers.
- I-44 and I-170 have consistently been less dependable.
c. Change in Total Congested Miles

Table 28: Total Congested Miles and \% Change by Interstate Freeway Corridors (2016-17)

| No. | Route | $\mathbf{2 0 1 6}$ | $\mathbf{2 0 1 7}$ | \% Change |
| :---: | :--- | ---: | ---: | :---: |
| 1 | I-44 | 35.17 | 15.41 | $-56 \%$ |
| 2 | I-55 | 24.16 | 2.89 | $-88 \%$ |
| 3 | I-64 | 61.54 | 54.84 | $-11 \%$ |
| 4 | I-70 | 64.90 | 42.88 | $-34 \%$ |
| 5 | I-170 | 20.16 | 13.00 | $-36 \%$ |
| 6 | I-270 | 59.03 | 47.29 | $-20 \%$ |
| TOTAL |  | $\mathbf{2 6 5}$ | $\mathbf{1 7 6}$ | $\mathbf{- 3 3 \%}$ |

- Queue lengths for major freeways have dropped by about $33 \%$ between 2016 and 2017.
- I-44 and I-55 registered most drop in queue lengths.
